Abstract

Mutation testing is injecting artificial faults into the code to assess the written test methods. Not surprisingly, this process is time-consuming and may take hours and days to complete. On the other hand, developers, who are busy with different tasks, may find it cumbersome to run mutation testing in their workstations. In this paper, we propose some steps to develop a zero-touch mutation testing framework and facilitate employing mutation testing by developers. We extend `MuTALK`, the mutation testing framework in the live programming environment of Pharo, by (1) adding hierarchical mutation operators, (2) integrating it to GitHub-Actions, (3) visualizing the result in a web-based mutants explorer.

Keywords

Mutation testing, Zero-touch testing, test amplification, Pharo

1. Introduction

Software is everywhere, and its failures cost. Unit testing is writing small test code snippets that exercise the unit under test and asserts the intended values. In mutation testing [1], some artificial bugs (mutations) are injected into the unit under test to evaluate the test suite's strength. We say the test suite kills the mutant if the injected bugs are detected. However, if the mutants remain alive, it shows that the test suite needs improvement.

Pharo [2, 3] is a dynamically typed language with a live programming environment focusing on simplicity and immediate feedback. The observations from the experiments in our past work in Pharo were the main motivation for this work. We developed a test amplification tool, `SMALL-AMP` [4], that analyzes the program under test and its test suite and suggests new test methods to kill some of the mutants. During the experiment, we noticed that `MuTALK`, the mutation testing in Pharo, generates too few mutants compared to the mutation testing framework in Java from another work [5]. Mutation testing in Pharo generated 1102 mutants for 52 classes (≈ 21 mutants per class), while there were 7980 mutants in 40 classes in Java (≈ 200 mutants per class). To the extent that in one of the cases (`TLLegendTest`), it failed to generate any mutant despite the class under

test having 96 lines of code. This observation led us to expand the mutation operator in `MuTALK` of which the details come in Section 2.

After adding new mutation operators, we witnessed that the number of times Pharo has recovered from freezing has increased, and the main reason was entering an infinite loop. Section 3 explains this problem with an example and how we overcome this problem.

In the next step, we created `MuTALKCI` as a zero-touch mutation testing for the live programming environment of Pharo. By default, developers are expected to use `MuTALK` manually by loading it in their Pharo image, running it over their project, and waiting a considerable time to finish. We created a workflow in GitHub-Actions that loads the project under test and runs a hierarchical mutation testing on it. We call it zero-touch because the burdensome parts of the process are automated, and the developers' attention is needed when the result is ready to be audited. `MuTALKCI` is explained in Section 4.

Finally, we designed a web-based mutant explorer to stash the mutation coverage status over the development time (similar to `coveralls.io` but for mutation testing). Using this mutant explorer, developers can assess the alive mutants and decide which to kill. We also equipped some coverage information based on the RIPR model [6, 7, 8, 9, 10] which helps developers in their assessment. This web interface is bidirectional and allows the developer to mark the mutants as to be killed, which creates an issue in the repository on GitHub. The interactive mutant explorer comes in Section 5.

2. Expanding Mutation Operators

Pharo is a pure object-oriented, dynamically typed language based on Smalltalk. It offers a simple language model: every action in the language is accomplished by sending messages to objects. In the context of Pharo, the term message sending is used instead of method invocation. As an example, there is no predefined `if` statement in the language: it is implemented as sending the message `ifTrue:` with a block argument to boolean objects.

Most original operators in `MuTALK` interchange the known messages with other known messages [11]. For example, they replace `ifTrue:` messages with `ifFalse:`. Other operators remove the function return operator, remove exception handling blocks, replace a block with an empty block, or replace the `ifTrue:` receiver object with `true/false` objects.

Learned from previous works and other mutation testing frameworks¹, we added the following new mutation operators to `MuTALK`². The list is sorted from the most coarse-grained to the finer operators:

- Extreme transformation. We adopted an extreme transformation operator [12, 13] that strips the whole body of the test method. In Pharo, these stripped methods always return their object (`^ self`). We use this operator as the most coarse-grained mutation that verifies whether the tests are sensitive to removing all statements from a covered method or not.

¹PIT: <https://pitest.org/quickstart/mutators/>

²<https://github.com/mabdi/mutalk>

- Disabling invocations. As we explained earlier, every action in Pharo is achieved by sending messages. The message `#yourself` is a special message that returns the object itself. We implemented a mutation operator that replaces the sent message with `#yourself` to disable an invocation. We use this operator as the second coarse mutation that verifies whether the tests are sensitive to disabling a statement from a covered method or not.
- Nullifying the arguments. In this mutation operator, we replace an argument in a message send node with `nil`. This operator also verifies whether the tests are sensitive to disabling an argument in one of the statements.
- Mutating the literals. In this mutation operator, we mutate the literal values. We use a negation for the Boolean constants, an increase/decrease or zero for the numerical constants, and replacing with an empty string or a specific predefined string for the string values.

3. Detecting Infinite Loops

After adding the new operators, we witnessed the number of times Pharo freezes has increased so that scarcely an execution finishes. The main freezing reason was entering an infinite loop. Here we explain it using an example. The left code in the Listing 2 shows a method in which the factorial of an integer number is calculated recursively. The code snippet on the right shows the same method after applying a mutation during mutation testing analysis. When MUTALK runs the test to verify mutation detection, an infinite loop happens because the mutation operator disables the conditional statement. Sometimes, the operating system kills the process by an Out of memory error.

Listing 1: Examples of an infinite loop after mutation testing.

<pre>f#=0factorial: a#=0anInt a#=0anInt == 1 i#=0ifTrue: [^ 1]. ^ a#=0anInt * (self f#=0factorial: a#=0anInt -1)</pre>	<pre>f#=0factorial: a#=0anInt (a#=0anInt == 1) yourself. ^ a#=0anInt * (self f#=0factorial: a#=0anInt -1)</pre>
--	---

The occurrence of the infinite loop is not limited to this mutation operator. Other mutations such as changing the condition to *false* (`false ifTrue: [^ 1]`), or removing the return operator from the block closure (`anInt == 1 ifTrue: [1]`) also lead the execution to an infinite loop.

In a language like Java, the mutation testing framework and the test runner run in two different processes. As a result, the test runner process fails with a `StackOverflow` error in a similar mutation and is detected effortlessly by mutation testing. However, the story is different in Pharo because it is a live programming environment. The mutation testing framework and the test runner run in a shared process called Pharo image. So, an infinite loop for the test runner means the whole process loses its availability. We explained this problem in [14].

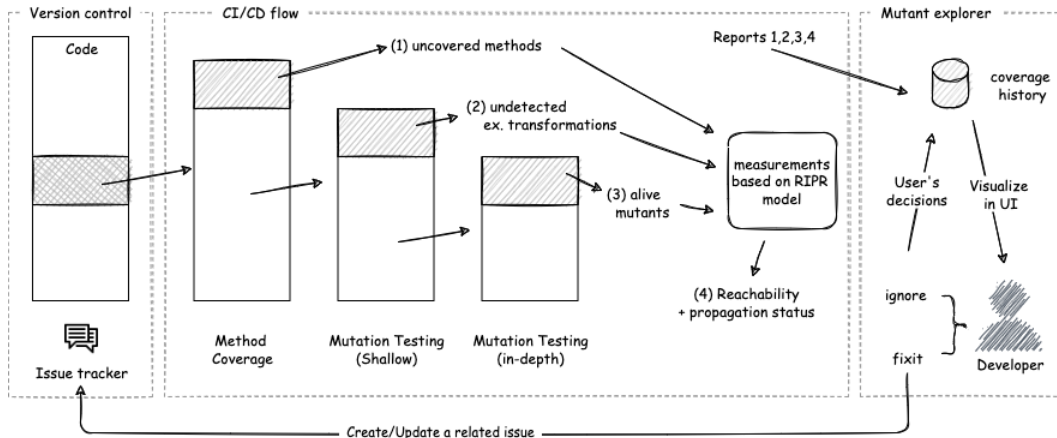

Figure 1: Hierarchical zero-touch mutation testing for Pharo

To solve this problem, we added an auxiliary statement at the beginning of the mutated method. This statement counts the number of its executions and throws an exception that fails the test if it reaches the defined threshold. We exploited the technique used in the class `Halt` in Pharo internals for its implementation. Although this technique significantly decreased the number of freezings, the process still may crash or freeze for other reasons. We leave recovering from other crashes as future work.

Listing 2: Auxiliary exception for avading infinite loops.

```
f#=0factorial: a#=0anInt
R#=0RecursionError o#=0onCount: 1024. "I will go off if executed 1024 times"
(a#=0anInt == 1) yourself.
^ a#=0anInt * (self f#=0factorial: a#=0anInt -1)
```

4. Zero-touch MuTalk

For using `MUTALK`, developers should perform some tedious tasks, including installing the tool on their Pharo image, initializing it, running it over their programs, and waiting a considerable time to obtain the results. These burdensome steps may hinder `MUTALK` from being used regularly. In this part, we propose a zero-touch mutation testing solution to automate the unnecessary involvement of developers.

Recently, mutation testing has been employed at scale in Google by integrating it into the build system and using a diff-based probabilistic approach to reduce the number of mutants [15]. Then in the code-review process, alive mutants are shown to developers, and they decide to kill or ignore them. In this part, we try to setup a similar process for Pharo's open-source projects.

Figure 1 illustrates the proposed hierarchical approach for running `MUTALK` in the CI/CD build servers. Similar to recent diff-based mutation testing works [16, 15], when

the workflow is triggered, it automatically finds new changes in the repository since the last execution. Then it runs a hierarchical analysis:

1. Firstly, it runs a code coverage tool to find the uncovered parts (report number 1: uncovered methods). If a method is not covered, all its mutants will survive, so we do not need to run mutation testing on it. So, we exclude all uncovered parts from the following analysis.
2. Then, a light mutation testing is executed (report number 2: undetected extreme transformations). In our implementation, we only use the extreme transformation operator. Similarly, if an extreme mutation on a method is not detected, we exclude it from the next analysis.
3. In the third step, a more detailed mutation testing, including all remained operators, is executed on the parts detected by the previous step, and report number 3 is formed.

Based on the RIPR model [6, 7, 8, 9, 10], we know that a mutant is killed when it is reached by a test (reachability); the program state is different from the state in the original version at that point (infection); the infected change is propagated to the state of the test (propagation); finally, the change is revealed by an assertion statement (reveal).

To help developers to kill the mutant manually, we provide two types of coverage status for alive mutants: the list of tests covering each alive mutant and the list of tests having a propagated change (report number 4). The tests covering a mutant are start points for manual investigations on how to kill a mutant. A method with a propagated change is also interesting for developers because it says that developers can kill the mutant only by adding an oracle statement to assert the state change caused by the mutation.

We developed a GitHub-Actions workflow³ that runs `MUTALK`, and exports the reports as json outputs. The outputs are sent to the mutants explorer API (See Section 5) using GitHub’s authenticated account token. We use GitHub-Actions because most of Pharo’s projects currently are hosted on GitHub, and it is freely available for all open-source projects.

5. Mutants Explorer

Since interpreting the reports generated in Section 4 may be cumbersome, we designed a web-based mutant explorer⁴. The explorer keeps the history of all builds (similar to coveralls) and visualizes mutants and their coverage status. Furthermore, it is interactive and allows developers to assess the mutants and decide whether they should be killed or ignored. If they decide a mutant to be killed, the explorer adds an item to a GitHub issue related to this build in the repository.

Figure 2 shows an example issue to remind the developer how to kill the mutant manually. The left figure is a mutant shown to the developer in which the mutated

⁴<https://github.com/harolato/mutation-testing-coverage>

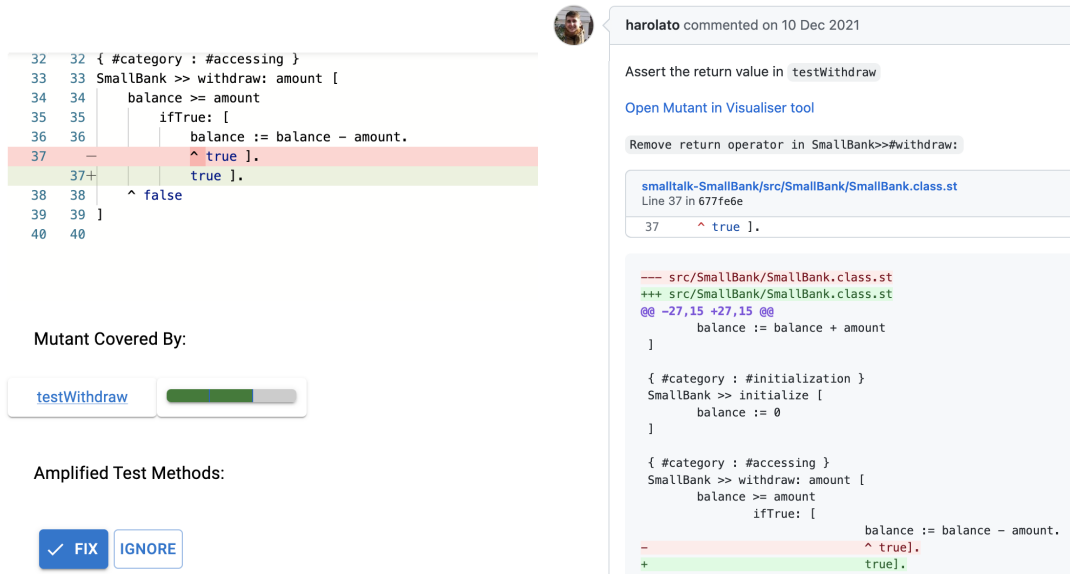

Figure 2: A mutant view and its generated issue

part is displayed as a diff view on top. Then test methods covering this method are listed. In this example, we see that `testWithdraw` not only covers the method (the first green block), but the state change from this mutant is propagated to its context (second green block). Using this report, developers understand that they can add an assertion statement to this test method to verify the method's return value `withdraw:` and kill the mutant. They can click the `FIX` button to add an issue (right figure) to the GitHub repository. Using GitHub's REST APIs and the user's token obtained with `oAuth`, the web interface creates an issue per build and appends all items to fix. Developers can refer to this issue later and amplify their tests manually by adding new test methods or updating their existing tests.

6. Conclusion and Future work

In this paper, we propose an approach to creating a zero-touch mutation testing framework with: (1) adding new mutation testing operators to `MUTALK` and use an approach to identify the infinite loops and evade freezings; (2) developing a zero-touch mutation testing to automate burdensome tasks by implementing a GitHub-Actions workflow that loads the project under test and `MUTALK`, and runs a mutation testing process; (3) the outputs are sent to a mutant explorer in which the history of mutations is recorded and allows developers to assess mutants and mark them as to be fixed. The assessments are collected in a GitHub issue that developers can refer to in the future to amplify the tests manually.

In future work, the system will be run in practice, and a user study will be conducted to evaluate it.
